## Introduction

- Metaplastic breast cancer (MBC) is a very rare type of invasive breast cancer (TNBC) that accounts for <1-5% of all breast cancers.</p>
- The majority of MBC are triple negative cancers; however the prognosis of MBC is generally worse than other triple negative breast cancers on average<sup>1</sup>.
- We aimed to compare disease free and overall survival between patients with MBC and those with non-metaplastic TNBC at OSUCCC James.
- In addition, we assessed expression of immune markers in the primary tumor and correlated with clinical outcomes.

#### Methods

- We retrospectively reviewed the clinical charts of 382 patients seen at OSUCCC – James between January 1, 1994 and December 31, 2014.
- Patients with MBC (n=44) were matched, using a 1 to 3 ratio, with non-metaplastic TNBC controls (n=130) by stage and age at diagnosis.
- Demographics and treatments were compared between MBC and TNBC controls, and multivariate analysis was performed to assess disease free survival (DFS) and overall survival (OS) outcomes between groups.
- Observation time was defined as the time from diagnosis to death or censoring.
- Samples from a small cohort of TNBC patients (n=119) and MBC patients (n=27) were used to assess immune marker staining.

# Results

- Median observation time was 2.8 years with only 8 patients followed for more than ten years.
- Taxane therapies were used less frequently for the treatment of MBC compared to TNBC patients (70.5% vs 85.4%, p=0.0411).
- Rates of disease free (p=0.35) and overall survival (p=0.32) were similar between MBC and TNBC patients.
- Risk of disease recurrence (HR=1.64, 95% CI=0.75-3.58, p=0.22) and death (HR=1.64, 95% CI=0.69-3.90, p=0.26) were also similar between MBC and TNBC patients
- Fewer MBC samples were positive for CD8 in tumor cells than TNBC samples (18.5% vs. 44.5%, p=0.0158).
- More MBC samples were positive for CD163 in stroma cells (96.3% vs. 79.8%, p=0.0468) and PD-L1 in tumor cells (29.6% vs. 10.1%, p=0.0133) than the TNBC samples.

Table 1: Demographics Characteristics					
Variable	Level	Triple negative n=130	Metaplastic n=44	Total	P-value
Age at diagnosis	Mean (SD)	54.6 (12.8)	55.4 (13.9)	54.8 (13.0) [n=174]	0.7495
Weight at diagnosis	Mean (SD)	170.3 (38.8)	166.8 (31.3)	169.4 (37.0) [n=171]	0.5977
Race	White	108 (83.1%)	40 (90.9%)	148 (85.1%)	0.2451
	Black	14 (10.8%)	4 (9.1%)	18 (10.3%)

### Discussion

- Contrary to previous publications<sup>2</sup>, our data suggests that patients with MBC had similar outcomes to TNBC based on disease free and overall survival.
- Use of taxane and anthracyclines based therapy was more common among our patients with MBC (70.5% and 77.3%) in comparison to other studies<sup>3,4</sup>.
- Lower CD8, higher CD163, and higher PD-L1 staining in our MBC samples is comparable to data from previous publications using samples associated with worse prognosis<sup>5,6</sup>.
- Future studies are needed to confirm the prognostic role of tumor PD-L1, stromal CD163, and tumor CD8 in MBC, and further research is needed to see if these are potential therapeutic targets.
- Metaplastic breast cancer is a rare disease with a small patient population, so a prospective study will be difficult.
- Our retrospective study gives some hope for patients with MBC, showing that their outcomes can be as good as those with TNBC when treated with appropriate adjuvant therapies.
